7CS033 Assignment Task 4

Complete the following tasks.

You should comment on your code where appropriate. Failing to add comments may result in a mark deduction.

You should write any explainations in the report cell if the task explicitly asks for this or if you wish to expand upon your solution.

Ensure you have ran your code cell and printed any of the required outputs. If necessary you can use more than one code cell.

Tasks

TASK 4.1: Download the adult_T4 dataset. Apply K-Means and Hierarchical clustering to three optional columns in the dataset. Find the optimum number of clusters for both clustering methods (10%).

NOTE: You should comment on your code wherever necessary and briefly explain what the code is doing

In [ ]:

############# WRITE YOUR REPORT IN THIS CELL (IF APPLICABLE)################### In this task, K-Means and Hierarchical clustering were applied to three numerical features: age, education-num, and hours-per-week. The data was standardised to ensure equal contribution of each feature to the distance calculations. The Elbow method and Silhouette score were used to determine the optimal number of clusters. For K-Means, the highest silhouette score was obtained at k = 4, indicating that four clusters provide the best separation and cohesion. For Hierarchical clustering, the highest silhouette score was observed at k = 8, although k = 4 produced a similar value. Overall, K-Means slightly outperformed Hierarchical clustering based on

silhouette score, suggesting clearer cluster separation in the selected feature space. To further examine cluster structure, 3D scatter plots were generated using the three selected features. The visualisations show moderate separation between clusters, although some overlap exists, which is consistent with the moderate silhouette scores. This suggests that while meaningful cluster structure is present, the boundaries between clusters are not sharply defined.

Task 4.2: Apply the PCA method to the dataset and extract the first two principal components (n_components=2). Plot the scatter plot of the dataset's first two components for the two classes of the income column (5%).

NOTE 1: You should comment on your code wherever necessary and briefly explain what the code is doing.

NOTE 2: You need to encode the categorical columns, normalise the dataset, and remove the income column before applying the PCA method.

# Plot each class separately
plt.scatter(X_pca[class_0, 0], X_pca[class_0, 1], label="Income <=50K", alpha=

plt.scatter(X_pca[class_1, 0], X_pca[class_1, 1], label="Income >50K", alpha=0

plt.xlabel("Principal Component 1")
plt.ylabel("Principal Component 2")
plt.title("PCA - First Two Components by Income Class")
plt.legend()
plt.show()
```

############# WRITE YOUR REPORT IN THIS CELL (IF APPLICABLE)################### Before applying PCA, categorical variables were encoded and the dataset was normalised. The income column was removed prior to dimensionality reduction. The first two principal components explained approximately 50% of the total variance in the dataset. A scatter plot of these components, coloured by income class (≤50K and >50K), showed noticeable overlap between the two classes. This suggests that income is not clearly separable in two-dimensional space and may depend on more complex feature interactions.
